- Brushes cannot traverse a clean edge.

We can get two different final configurations but the final set of dirty vertices is determined.

Theorem (Messinger, Nowakowski, Pralat)

Given a graph G and the initial configuration of brushes $\omega_0 : V \to \mathbb{N} \cup \{0\}$, the cleaning algorithm returns a unique final set of dirty vertices.

We can get two different final configurations but the final set of dirty vertices is determined.

Theorem (Messinger, Nowakowski, Pralat)

Given a graph G and the initial configuration of brushes $\omega_0: V \to \mathbb{N} \cup \{0\}$, the cleaning algorithm returns a unique final set of dirty vertices.

ヘロト 人間 ト 人 ヨ ト 人 ヨ ト

Thus, the following definition is natural.

Definition (brush number)

A graph G = (V, E) can be cleaned by the initial configuration of brushes ω_0 if the cleaning process returns an empty final set of dirty vertices.

Let the brush number, b(G), be the minimum number of brushes needed to clean G, that is,

$$b(G) = \min_{\omega_0: V \to \mathbb{N} \cup \{0\}} \Big\{ \sum_{v \in V} \omega_0(v) : G \text{ can be cleaned by } \omega_0 \Big\}.$$

Similarly, $b_{\alpha}(G)$ is defined as the minimum number of brushes needed to clean *G* using the cleaning sequence α .

yielding final configuration ω_n , n = |V(G)|. Then, given the initial configuration $\tau_0 = \omega_n$, G can be cleaned yielding the final configuration $\tau_n = \omega_0$.

・ 同 ト ・ ヨ ト ・ ヨ ト …

The cleaning process is a combination of both

- the edge-searching problem:
 - modeling sequential computation,
 - assuring privacy when using bugged channels,
 - VLSI circuit design,
 - security in the web graph.
- the chip firing game:
 - the Tutte polynomial and group theory,
 - algebraic potential theory (social science).

There is also a relationship between the Cleaning problem and the Balanced Vertex-Ordering problem (this has consequences for both problems).

Pairing model:

The probability of a random pairing corresponding to a given simple graph *G* is independent of the graph, hence the restriction of the probability space of random pairings to simple graphs is precisely $\mathcal{G}_{n,d}$.

Moreover, a random pairing generates a simple graph with probability asymptotic to $e^{(1-d^2)/4}$ depending on *d*.

Therefore, any event holding a.a.s. over the probability space of random pairings also holds a.a.s. over the corresponding space $\mathcal{G}_{n,d}$.

The first vertex cleaned must start three brush paths, the last one terminates three brush paths, and all other vertices must start or finish at least one brush path, so the number of brush paths is at least n/2 + 2.

It is known that a random 3-regular graph a.a.s. has a Hamilton cycle. The edges not in a Hamilton cycle must form a perfect matching. Such a graph can be cleaned by starting with three brushes at one vertex, and moving along the Hamilton cycle with one brush, introducing one new brush for each edge of the perfect matching.

Then this, together with the first moment principle, gives that the brush number is a.a.s. at least *yn*.

In order to find an optimal values of x and y we use the pairing model. It is clear that

$$S(x,y) = \binom{n}{xn} \binom{xdn}{yn} M(xdn - yn) \binom{(1-x)dn}{yn} (yn)!$$

$$\times M((1-x)dn - yn)/M(dn)$$

where M(i) is the number of perfect matchings on *i* vertices, that is,

$$M(i) = rac{i!}{(i/2)!2^{i/2}}$$

ヘロン 人間 とくほ とくほ とう

э.

After simplification and using Stirling's formula we get that $S(x, y) < O(n^{-1})e^{f(x, y, d)}$ where

$$f(x, y, d) = x(d-1)\ln x + (1-x)(d-1)\ln(1-x) +0.5d\ln d - y\ln y -0.5(xd-y)\ln(xd-y) -0.5((1-x)d-y)\ln((1-x)d-y).$$

Thus, if f(x, y, d) = 0, then S(x, y) tends to zero with *n* and the brush number is at least *yn* a.a.s.

ヘロン 人間 とくほ とくほ とう

э.

After simplification and using Stirling's formula we get that $S(x, y) < O(n^{-1})e^{f(x, y, d)}$ where

$$f(x, y, d) = x(d-1)\ln x + (1-x)(d-1)\ln(1-x) +0.5d \ln d - y \ln y -0.5(xd-y)\ln(xd-y) -0.5((1-x)d-y)\ln((1-x)d-y).$$

Thus, if f(x, y, d) = 0, then S(x, y) tends to zero with *n* and the brush number is at least *yn* a.a.s.

▲ロト ▲掃 ト ▲ 臣 ト ▲ 臣 ト ○ 臣 - の Q ()

Not surprisingly, the strongest bound is obtained for x = 1/2, in which case f(x, y, d) becomes

$$(d-1)\ln(1/2) + (d/2)\ln d - y\ln y - (d/2 - y)\ln(d/2 - y)$$
$$= -\frac{d}{4}((1+z)\ln(1+z) + (1-z)\ln(1-z)) + \ln 2$$

where
$$y = (d/4)(1 - z)$$
.

It is straightforward to see that this function is decreasing in z for $z \ge 0$. Let I_d/n denote the value of y for which it first reaches 0.

Since the Taylor expansion of $(1 + z) \ln(1 + z) + (1 - z) \ln(1 - z)$ is $z^2 + z^4/6 + ..., I_d/n \ge (d/4)(1 - 2\sqrt{\ln 2}/\sqrt{d}).$

Not surprisingly, the strongest bound is obtained for x = 1/2, in which case f(x, y, d) becomes

$$(d-1)\ln(1/2) + (d/2)\ln d - y\ln y - (d/2 - y)\ln(d/2 - y)$$
$$= -\frac{d}{4}((1+z)\ln(1+z) + (1-z)\ln(1-z)) + \ln 2$$

where y = (d/4)(1 - z).

It is straightforward to see that this function is decreasing in *z* for $z \ge 0$. Let l_d/n denote the value of *y* for which it first reaches 0.

Since the Taylor expansion of $(1 + z) \ln(1 + z) + (1 - z) \ln(1 - z)$ is $z^2 + z^4/6 + ..., I_d/n \ge (d/4)(1 - 2\sqrt{\ln 2}/\sqrt{d}).$

Lemma (Expander Mixing Lemma; Alon, Chung, 1988)

Let G be a d-regular graph with n vertices and set $\lambda = \lambda(G)$. Then for all S, T \subseteq V

$$\left| |E(S,T)| - \frac{d|S||T|}{n} \right| \leq \lambda \sqrt{|S||T|}.$$

(Note that $S \cap T$ does not have to be empty; |E(S, T)| is defined to be the number of edges between $S \setminus T$ to T plus twice the number of edges that contain only vertices of $S \cap T$.)

・ 戸 ト ・ ヨ ト ・ ヨ ト

Nonconstructive proof:

Let *G* be **any** *d*-regular graph. Let π be a random permutation of the vertices of *G* taken with uniform distribution. We clean *G* according to this permutation.

We have to assign to vertex v exactly

 $X(v) = \max\{0, 2N^+(v) - \deg(v)\}$

brushes in the initial configuration, where $N^+(v)$ is the number of neighbors of v that follow it in the permutation.

The random variable $N^+(v)$ attains each of the values $0, 1, \ldots, d$ with probability 1/(d + 1).

Nonconstructive proof:

Let *G* be **any** *d*-regular graph. Let π be a random permutation of the vertices of *G* taken with uniform distribution. We clean *G* according to this permutation.

We have to assign to vertex v exactly

$$X(v) = \max\{0, 2N^+(v) - \deg(v)\}$$

brushes in the initial configuration, where $N^+(v)$ is the number of neighbors of v that follow it in the permutation.

The random variable $N^+(v)$ attains each of the values 0, 1, ..., *d* with probability 1/(d+1).

ヘロン 人間 とくほ とくほ とう

Therefore the expected value of X(v), for even d, is

$$\frac{d+(d-2)+\cdots+2}{d+1}=\frac{d+1}{4}-\frac{1}{4(d+1)},$$

and for odd d it is

$$\frac{d + (d-2) + \dots + 1}{d+1} = \frac{d+1}{4}.$$

Thus, by linearity of expectation,

$$\mathbb{E}b_{\pi}(G) = \mathbb{E}\left(\sum_{v \in V} X(v)\right) = \sum_{v \in V} \mathbb{E}X(v)$$
$$= \begin{cases} \frac{n}{4}\left(d+1-\frac{1}{d+1}\right) & \text{if } d \text{ is even} \\ \frac{n}{4}(d+1) & \text{if } d \text{ is odd,} \end{cases}$$

which means that there is a permutation π_0 such that $b(G) \le b_{\pi_0}(G) \le \mathbb{E}b_{\pi}(G)$.

Pawel Pralat Cleaning random *d*-regular graphs with brushes and Brooms

Therefore the expected value of X(v), for even d, is

$$\frac{d+(d-2)+\cdots+2}{d+1}=\frac{d+1}{4}-\frac{1}{4(d+1)},$$

and for odd d it is

$$\frac{d + (d - 2) + \dots + 1}{d + 1} = \frac{d + 1}{4}.$$

Thus, by linearity of expectation,

Theorem (Pralat (cleaning along the Hamilton cycle))

Let $G \in \mathcal{G}_{n,d}$, where $d \ge 3$. Then, a.a.s., if d is even

$$B(G) \geq \frac{n}{4} \left(d + 3 + \frac{3}{d-1} - 2^{-d+4} \binom{d-2}{d/2-1} \right) (1+o(1))$$

and if d is odd then

$$B(G) \geq \frac{n}{4} \left(d + 3 + \frac{4}{d-1} - 2^{-d+3} \frac{d}{d-1} \binom{d-1}{(d-1)/2} \right) (1+o(1))$$

Degree-greedy algorithm yields the best lower bound (numerical).

3

The *brush* number: $b(G) = \min_{\alpha} b_{\alpha}(G)$.

The *Broom* number: $B(G) = \max_{\alpha} b_{\alpha}(G)$.
